

Date: 01-06-2026 (Monday)

My objectives for the day:

To understand pod creation in a cloud environment, learn resource selection, and practice launching JupyterLab using GPU support for notebook-based work.

List of activities I did today:

Observed the complete pod creation workflow in the working environment and noted the sequence of setup steps.

Understood how CPU, memory, storage, and GPU resources are allocated to a pod before launch.

Launched JupyterLab using a GPU-enabled configuration and checked whether the environment opened correctly.

Verified notebook access, basic interface setup, kernel readiness, and availability of required tools.

Noted how configuration choices affect startup time and overall usability of the environment.

My critical observation:

GPU-backed notebook environments work efficiently only when the correct compute resources, runtime settings, and startup configuration are selected in advance. Small mistakes in setup can delay access or lead to failed launches, which shows the importance of careful configuration.

What did I learn today:

Learned the purpose of pod creation, how resource allocation supports execution, and the exact process used to launch JupyterLab with GPU access. Also understood why environment preparation is important for machine learning and notebook-based experimentation.

What I would have done better:

Could have documented each setup step more carefully, taken clearer notes on configuration options, and compared more than one launch setting for better understanding. A short checklist would also have helped reduce repeated trial and error during setup.

My plan for tomorrow:

Revise today's setup process once again and begin studying the fundamentals of artificial intelligence and machine learning with examples and key definitions.

Date: 02-06-2026 (Tuesday)

My objectives for the day:

To understand the meaning of artificial intelligence, identify its scope, and study the basic concepts that form the foundation of machine learning.

List of activities I did today:

Studied the definition of artificial intelligence and discussed how machines can simulate intelligent behavior.

Explored the difference between AI, machine learning, deep learning, and basic automation systems.

Learned machine learning concepts such as data, features, models, training, testing, and prediction.

Discussed supervised and unsupervised learning at a basic level with simple real-world examples.

Observed how learning from data helps systems improve decisions without explicit rule-based programming.

My critical observation:

Machine learning is a practical branch of AI that depends strongly on useful data, correct model design, and repeated training. The quality of input data greatly influences the quality of prediction, which makes data understanding as important as algorithm selection.

What did I learn today:

Learned the fundamentals of AI, the role of machine learning within AI, and how data-driven systems make predictions or support decisions. Also understood that machine learning focuses on finding patterns from examples rather than following only fixed instructions.

What I would have done better:

Could have compared more real-world use cases from healthcare, finance, and daily applications to strengthen understanding. Spending more time on the differences between rule-based systems and learning systems would have improved clarity further.

My plan for tomorrow:

Continue with the study of neural networks and understand how neurons, layers, weights, and activation functions work together in a model.

My objectives for the day:**Date: 03-06-2026 (Wednesday)**

To study neural networks, understand their internal structure, and learn how layered computation helps machines recognize patterns from input data.

List of activities I did today:

Learned the concept of artificial neurons and how they are inspired by biological neurons.

Studied the roles of input, hidden, and output layers in a simple neural network structure.

Understood how weights and biases influence the output produced at each stage of computation.

Reviewed activation functions and why non-linearity is important in solving complex problems.

Observed how data moves forward through a network during prediction or classification tasks.

Discussed basic examples showing how neural networks can model relationships in data.

My critical observation:

Neural networks improve their performance by adjusting weights and biases across multiple layers during learning. Even simple networks can represent useful patterns, but their behavior becomes easier to understand when each layer is studied step by step.

What did I learn today:

Learned the structure of neural networks and the function of neurons, layers, weights, biases, and activation functions. Also understood that layered computation allows the network to transform raw input into more meaningful internal representations.

What I would have done better:

Could have practiced with a small diagram or handwritten example to connect theory with implementation more effectively. Solving one sample forward-pass calculation would also have improved confidence in the topic.

My plan for tomorrow:

Move on to deep learning concepts and understand how deeper neural networks improve feature learning in more complex tasks.

Date: 04-06-2026 (Thursday)

My objectives for the day:

To understand deep learning, relate it to neural networks, and study why deeper models are useful for solving complex data problems.

List of activities I did today:

Studied the meaning of deep learning and its dependence on multi-layer neural network models.

Compared deep learning with traditional machine learning and simpler neural network approaches.

Learned how multiple hidden layers help in extracting features at different levels of abstraction.

Reviewed examples of deep learning applications such as image recognition, speech processing, and language tasks.

Observed the importance of large datasets and computational power in training deep models.

Prepared a short comparison between shallow models and deep architectures for revision.

My critical observation:

Deep learning becomes more powerful as model depth increases, but it also requires larger datasets, more computation, and careful tuning. Better performance usually comes with higher training cost, which makes both hardware support and model design important.

What did I learn today:

Learned that deep learning uses many hidden layers to automatically extract complex patterns from data with reduced manual feature engineering. Also understood why deep models are widely used in domains where raw data is large, rich, and unstructured.

What I would have done better:

Could have explored more practical use cases and compared specific examples to better understand where deep learning performs best. Reading one simple model workflow in detail would have made the topic more concrete.

My plan for tomorrow:

Study the antigravity tool, revise full stack development basics, and relate tools and concepts to complete application development.

Student Signature: 

Faculty-in-Charge Signature: 

My objectives for the day:

Date: 05-06-2026 (Friday)

To learn about the antigravity tool, understand its purpose, and revise the basic concepts involved in full stack development.

List of activities I did today:

Observed the purpose and usage of the antigravity tool in the learning workflow.

Studied the basic roles of front-end, back-end, and database components in application development.

Understood how user interfaces interact with server-side logic to process requests and return results.

Reviewed the role of databases in storing, retrieving, and updating application data reliably.

Discussed how all layers of a full stack system work together to deliver a complete software solution.

Prepared revision points on integration between client side, server side, and persistent storage.

My critical observation:

Full stack development requires coordination between interface design, server logic, and data management to create a complete and usable system. Understanding each layer separately is useful, but understanding their interaction is what makes the overall workflow clear.

What did I learn today:

Learned the basic role of the antigravity tool and revised the foundation of full stack development across front end, back end, and database layers. Also understood how integrated development supports complete application building rather than isolated component work.

What I would have done better:

Could have connected the concepts with a small project example showing page flow, server processing, and database interaction. A visual architecture diagram would have made the relationship between layers easier to remember.

My plan for tomorrow:

Revise all topics learned during the week, organize notes clearly, and prepare a concise summary for future reference and discussion.
